Linear Methods in Causal Inference

POLI784

Linear estimators

- ▶ Suppose we have a sample of N units and observe the outcome Y_i , the treatment D_i , and the covariates \mathbf{X}_i .
- ▶ A linear estimator $\hat{\tau}$ takes the form

$$\hat{\tau} = \sum_{i=1}^N w(D_i, \mathbf{X}_i) * Y_i.$$

- ▶ A linear combination of Y_i .

Linear estimators

- ▶ For example, if Y_i and D_i are mean-zero and there are no covariates, the regression coefficient equals

$$\hat{\tau} = \frac{\sum_{i=1}^N D_i Y_i}{\sum_{i=1}^N D_i^2}$$

- ▶ Here $w(D_i, \mathbf{X}_i) = \frac{D_i}{\sum_{i=1}^N D_i^2}$.
- ▶ It can be more complicated and covers most methods we have for causal inference.
- ▶ Another example is the nearest-neighbor matching estimator:

$$\hat{\tau} = \frac{1}{N_1} \sum_{i:D_i=1} (Y_i - Y_{N_i}),$$

where Y_{N_i} is i 's nearest neighbor from the control group.

Estimator, estimate, and estimand

- ▶ An estimator is a mapping from your data to a number (or several numbers).
- ▶ You can think of it as an algorithm (e.g., sample average $\hat{\tau} = \frac{1}{N} \sum_{i=1}^N Y_i$).
- ▶ Also known as a functional (a function of the distribution function).
- ▶ The number we obtain is called an estimate.
- ▶ We hope the estimator has good properties: the estimate it generates should be close to a theoretical quantity τ we care about.
- ▶ Such a quantity is referred to as the estimand or the target parameter.
- ▶ The estimand should be justified by our substantive arguments.

Estimator, estimate, and estimand

- ▶ The estimand may depend on variables not in our data.
- ▶ Suppose we have missing data in the sample and observe $Y_i = Y_i^*$ only when $S_i = 1$.
- ▶ The estimand, population mean, depends on Y_i^* .
- ▶ But our estimator can only depend on Y_i and S_i .

Identification

- ▶ If the estimate generated by the estimator equals the estimand τ when N is infinite, we say τ can be identified.
- ▶ Identification means whether we can infer the value of the target parameter at least in theory.
- ▶ In the previous example, it means we can find an estimator $\hat{\tau}$ such that $E[Y_i] = E[\hat{\tau}]$.
- ▶ Whether this is possible depends on assumptions we have imposed.

Properties of an estimator

- ▶ If $E[\hat{\tau}] = \tau$, we say the estimator is unbiased for τ .
- ▶ If there exists an unbiased estimator for τ , then τ can be identified.
- ▶ If $\lim_{N \rightarrow \infty} \hat{\tau} = \tau$, we say the estimator is consistent.
- ▶ Consistency holds when the variance of the estimator declines to zero:

$$P(|\hat{\tau} - \tau| > \varepsilon) \leq \frac{\text{Var}(\hat{\tau} - \tau)}{\varepsilon^2}. \text{ (Markov's inequality)}$$

- ▶ It is essentially the proof of the law of large numbers.

An example: sample average

- ▶ What are the properties of the sample average estimator?
- ▶ Suppose
 1. $Y_i \sim F(y)$, $E[Y_i] = \mu$,
 2. $\text{Var}[Y_i] = \sigma^2 < \infty$, and
 3. data are i.i.d. (independent and identically distributed)
- ▶ Remember that $\sigma^2 = E[Y_i^2] - \mu^2$.
- ▶ It is unbiased: $E[\hat{\tau}] = \frac{1}{N} \sum_{i=1}^N E[Y_i] = \frac{1}{N} \sum_{i=1}^N \mu = \mu$.

An example: sample average (*)

- ▶ The variance of the estimator is

$$\begin{aligned}\text{Var}[\hat{\tau}] &= E[\hat{\tau}^2] - (E[\hat{\tau}])^2 = E\left[\frac{1}{N^2} \sum_{i=1}^N \sum_{j=1}^N Y_i Y_j\right] - \mu^2 \\ &= \frac{1}{N^2} \sum_{i=1}^N E[Y_i^2] + \frac{1}{N^2} \sum_{i=1}^N \sum_{j \neq i} E[Y_i Y_j] - \mu^2 \\ &= \frac{1}{N^2} \sum_{i=1}^N (\sigma^2 + \mu^2) + \frac{1}{N^2} \sum_{i=1}^N \sum_{j \neq i} \mu^2 - \mu^2 \\ &= \frac{1}{N^2} \sum_{i=1}^N \sigma^2 = \frac{\sigma^2}{N} \rightarrow 0.\end{aligned}$$

- ▶ It is thus consistent.

Estimator, estimate, and estimand

- ▶ Consistency and unbiasedness do not imply each other.
- ▶ What estimator is consistent but biased?
- ▶ What estimator is unbiased yet inconsistent?
- ▶ Usually consistency is more important as we focus on large samples in social science.
- ▶ Unbiasedness matters more if the sample size is smaller.

From identification to estimation

- ▶ If an estimand can be identified, usually it can be estimated in finite sample.
- ▶ A common principle is to rely on the sample analogue.
- ▶ We replace the expectation sign $E[\cdot]$ with sample average $\frac{1}{N} \sum_{i=1}^N \cdot$.
- ▶ Identification is hard while estimation is easier.
- ▶ The estimate is the first number you are going to report in your quantitative analysis.
- ▶ It is important to discuss the magnitude of the estimate!
- ▶ Sometimes this is referred to as the economic significance of your estimate.
- ▶ It has welfare implications.

From estimation to inference

- ▶ But we also want to let our readers know how confident we are in the estimate.
- ▶ We want to construct confidence intervals for the estimate (often 95%).
- ▶ This process is called statistical inference.
- ▶ We can replace confidence intervals with confidence sets when the estimand is multi-dimensional.

Statistical inference

- ▶ First, we want to derive the theoretical variance of $\hat{\tau}$, $Var(\hat{\tau})$.
- ▶ If possible, we hope that $Var(\hat{\tau})$ is as small as possible (efficiency).
- ▶ $Var(\hat{\tau}) = E[\hat{\tau} - \tau]^2$ when $\hat{\tau}$ is unbiased.
- ▶ We have seen that if $Var(\hat{\tau}) \rightarrow 0$ when $N \rightarrow \infty$, $\hat{\tau}$ is consistent.
- ▶ It is often essential to know how fast $Var(\hat{\tau})$ declines to zero.

Statistical inference

- ▶ For most estimators, $N * \text{Var}(\hat{\tau})$ converges to a constant.
- ▶ Then, we have that $\sqrt{N}(\hat{\tau} - \tau)$ converges to a fixed distribution.
- ▶ We say $\hat{\tau}$ is root-N consistent.
- ▶ As we will see, most nonparametric estimators are not root-N consistent.
- ▶ For example, if $\hat{\tau}$ is based on kernel regression, then $N^{2/5}(\hat{\tau} - \tau)$ converges to a fixed distribution (under regularity conditions).

Statistical inference

- ▶ The variance's value hinges on this unknown parameter τ .
- ▶ We also need to find an estimate for $N * Var(\hat{\tau})$, denoted as $\hat{\sigma}^2$.
- ▶ We call $\frac{\hat{\sigma}}{\sqrt{N}}$ the standard error of $\hat{\tau}$.
- ▶ This becomes another estimation problem.
- ▶ We hope our variance estimate to be unbiased and consistent.
- ▶ At least, it should be conservative: $\hat{\sigma}^2 \geq N * Var(\hat{\tau})$ when $N \rightarrow \infty$.
- ▶ This is usually the second number you report in your analysis.

Statistical inference

- ▶ To construct confidence intervals, we need to know the distribution of $\hat{\tau}$, $F_N(\hat{\tau})$ even when $\hat{\tau}$ is root- N consistent.
- ▶ When N is finite, it is often impossible to know the answer.
- ▶ But as N is sufficiently large, the distribution is often close to the normal distribution: $\mathcal{N}(\tau, N * \text{Var}(\hat{\tau}))$.
- ▶ This is justified by the central limit theorem (CLT):

$$\sqrt{N}(\hat{\tau} - \tau) \rightarrow \mathcal{N}(0, N * \text{Var}(\hat{\tau})).$$

- ▶ Remember that our estimators have the linear form, hence they often converge to normality.

Statistical inference

- ▶ Another approach is to approximate $F_N(\hat{\tau})$ with resampling techniques.
- ▶ Common choices: jackknife and bootstrap.
- ▶ If we can approximate $F(\hat{\tau})$, we can construct the confidence intervals as

$$\hat{\mathcal{C}} = \left[\hat{\tau} - z_{1-\alpha/2} \frac{\hat{\sigma}}{\sqrt{N}}, \hat{\tau} + z_{1-\alpha/2} \frac{\hat{\sigma}}{\sqrt{N}} \right]$$

- ▶ What is the interpretation of the confidence interval?
- ▶ Remember that $\hat{\mathcal{C}}$ is an approximation!

Statistical inference

- ▶ Confidence intervals are closely connected with hypothesis testing.
- ▶ Under the null hypothesis $H_0 : \tau = 0$, we know that

$$\frac{\hat{\tau}}{\sqrt{\text{Var}(\hat{\tau})}} \rightarrow \mathcal{N}(0, 1)$$

- ▶ α is called the level of the test.
- ▶ A critical property of the confidence interval is the coverage rate, defined as

$$P(\tau \in \hat{\mathcal{C}}).$$

- ▶ We hope the coverage rate is at least $(1 - \alpha)\%$ when $N \rightarrow \infty$:

$$\lim_{N \rightarrow \infty} P(\tau \in \hat{\mathcal{C}}) \geq (1 - \alpha).$$

An example: sample average (continued)

- ▶ We can prove that the sample average is efficient.
- ▶ We can estimate its variance via either $\frac{1}{N} \sum_{i=1}^N (Y_i - \bar{Y})^2$ or $\frac{1}{N-1} \sum_{i=1}^N (Y_i - \bar{Y})^2$.
- ▶ Both variance estimators are consistent but only the latter is unbiased.
- ▶ We can show that $\sqrt{N}(\hat{\tau} - \tau) \rightarrow \mathcal{N}(\tau, \sigma^2)$ using the CLT.
- ▶ The 95% confidence interval of $\hat{\tau}$ can be conducted using critical values from the normal distribution.

Monte Carlo experiment

- ▶ With real data, we never know what the true DGP or the estimand is.
- ▶ But we can specify them in simulation, or Monte Carlo experiments.
- ▶ It is thus important to examine the performance of any method via simulation.
- ▶ We generate the data from a distribution that satisfies the requirement of the method.
- ▶ We apply the method to the data, obtaining all the quantities we need (the estimate, the variance estimate, the confidence interval, etc.).
- ▶ Remember that we can do this repeatedly and allow N to increase.

Monte Carlo experiment: sample average

```
N <- 100
Nboots <- 1000
ests <- matrix(NA, Nboots, 3)
covered <- rep(NA, Nboots)
for (b in 1:Nboots){
  Y <- runif(N) # population mean: 0.5
  # true variance is 1/12 = 0.0833
  Y_bar <- mean(Y)
  Y_var1 <- var(Y)
  Y_var2 <- var(Y) * (N / (N - 1))
  ests[b, 1] <- Y_bar
  ests[b, 2] <- Y_var1
  ests[b, 3] <- Y_var2
  CI <- c(Y_bar - 1.96 * sqrt(Y_var1 / N),
          Y_bar + 1.96 * sqrt(Y_var1 / N))
  covered[b] <- CI[1] <= 0.5 & CI[2] >= 0.5
}
```

Monte Carlo experiment: sample average

Monte Carlo experiment: sample average

```
mean(ests[, 1]) - 0.5 # bias
```

```
## [1] 0.0008474082
```

```
N*var(ests[, 1]) # true variance (simulated)
```

```
## [1] 0.0752958
```

```
mean(ests[, 2]) # avg. of estimated variance
```

```
## [1] 0.08375943
```

```
mean(ests[, 3]) # avg. of estimated variance
```

```
## [1] 0.08460549
```

```
mean(covered) # coverage rate
```

```
## [1] 0.953
```

Summary

- ▶ In social science research, we try to estimate a parameter or test a relationship.
- ▶ For this purposes, we collect a dataset and apply a method.
- ▶ The method should provide you with an estimate, a variance estimate, and confidence intervals at desirable levels.
- ▶ Therefore, to understand each method, we need to discuss under what circumstances its outputs are what we want.
